I. DEVELOPMENT OF GENERAL ALGORITHMS

A. INTRODUCTION

The procedure for the design of lowpass, highpass, bandpass, and bandstop digital filters from lowpass prototypes is well established, and is based on transforming the prototype frequency response to meet desired characteristics. This transformation can be accomplished in either the analog (s) domain or the digital (z) domain (Figure 1).

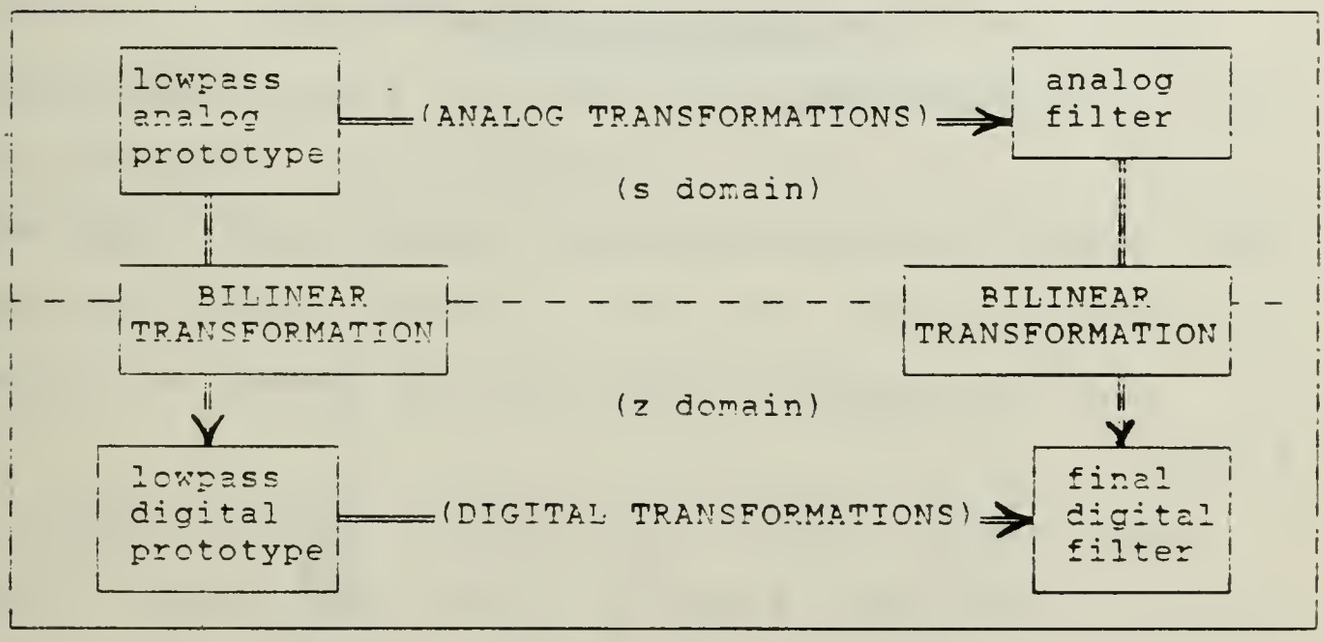

Figure 1. Two methods for digital filter design. Note that each of the horizontal arrows actually represent four different transformations:
1) lowpass prototype to lowpass filter
2) lowpass prototype to highpass filter
3) lowpass prototype to bandpass filter
4) lowpass prototype to bandstop filter

Therefore, the two classical design techniques, analog-digital and digital-digital design, are based on doing the frequency response transformations in their respective analog or digital domains. Since the theory for the standard filter types (Butterworth, Chebyshev, and elliptic) is developed in the analog or 's' domain, the two methods for designing digital filters differ basically in the sequence of the design steps. In the analog-digital method the analog prototype is transformed and then digitized, while in the digital-digital method the analog prototype is digitized and then transformed.

Each of the transformations (arrows in Figure 1) involves substituting a function of 's' or 'z' for the appropriate variable in the filter transfer function. The purpose of this thesis is to develop efficient algorithms to carry out these transformations and then to implement these algorithms in a computer program to aid in the design of digital filters.

Computer-aided design of digital filters offers a significant advantage since it allows the digital filter coefficients to be calculated quickly and accurately. The accuracy of the filter coefficients is an especially significant point since the frequency response of the final filter is very sensitive to small inaccuracies in the calculated coefficients. As an example, compare the frequency response for the filters in Figure 2 and 3. Figure

2 shows the frequency response magnitude for a 1/2-dB ripple Chebyshev bandpass filter, and Figure 3 shows the frequency response when one of the coefficients has been changed by 1/1000th.

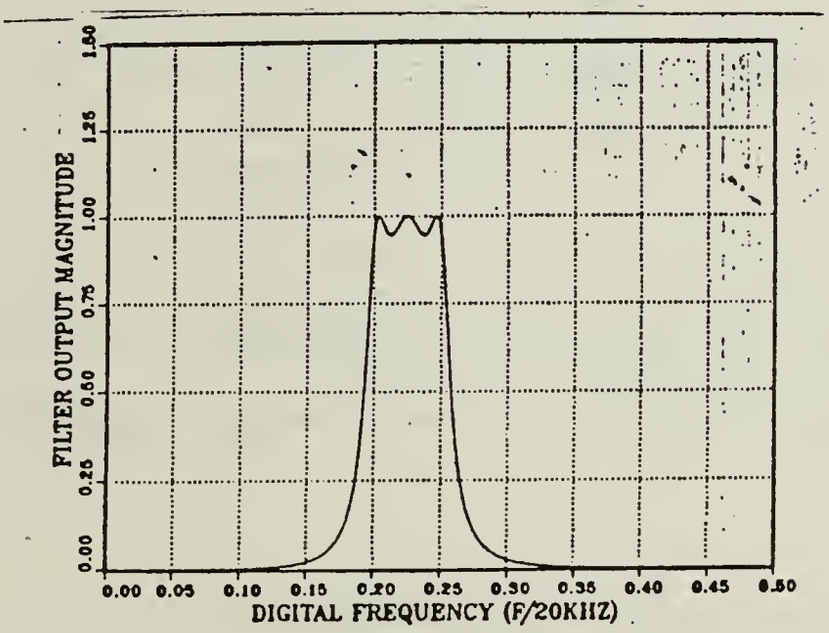

Figure 2. Chebyshev Bandpass Filter

$$H(z) = \frac{.00229(z^4 - 1)^3}{z^6 - .87775z^5 + 2.80076z^4 - 1.5389z^3 + 2.46277z^2 - .67494z + .67529}$$

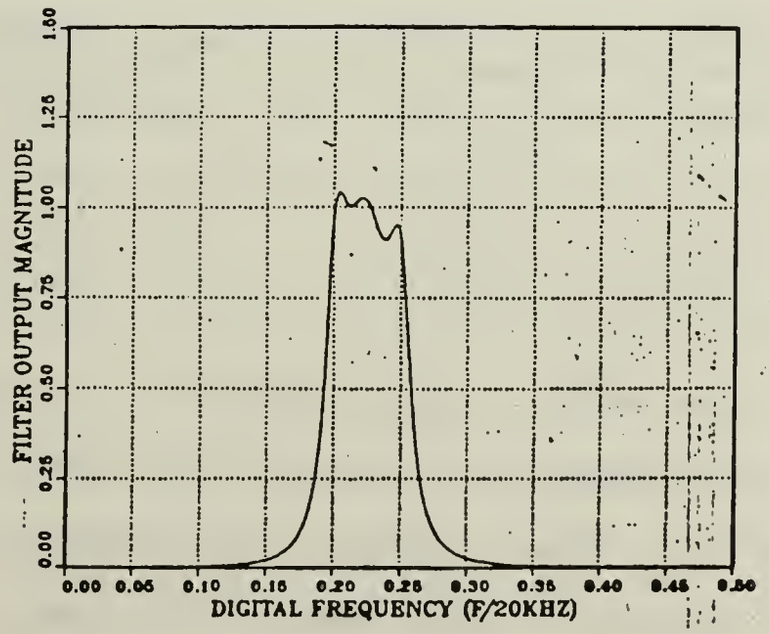

Figure 3. Same Filter With Denominator Coefficient of z changed to -.67594

B. GENERAL DISCUSSION

Each of the transformations involves substituting a ratio of two polynomials of s or z into the filter transfer function which is also a ratio of two polynomials in s or z, namely

$$H(y)=\left.\frac{Y(y)}{U(y)}\right|_{y=\frac{p(x)}{q(x)}} \qquad (1.1)$$

The variables 'x' and 'y' can be either 's' or 'z' depending on the transformation to be performed. Therefore, we have either

$$H(y)=\left.\frac{a_0 + a_1 y + a_2 y^2 + \ldots + a_m y^m}{b_0 + b_1 y + b_2 y^2 + \ldots + b_n y^n}\right|_{y=\frac{p(x)}{q(x)}} \qquad (1.2)$$

or

$$H(x)=\frac{a_0 + a_1 \frac{p(x)}{q(x)} + a_2 \frac{(p(x))^2}{(q(x))^2} + \ldots + a_m \frac{(p(x))^m}{(q(x))^m}}{b_0 + b_1 \frac{p(x)}{q(x)} + b_1 \frac{(p(x))^2}{(q(x))^2} + \ldots + b_n \frac{(p(x))^n}{(q(x))^n}} \quad . \qquad (1.3)$$

In general, the order of the numerator 'm', is less than the order of the denominator 'n' (except for the transformations in the digital domain where the result of the bilinear transformation is to make n=m). We can generalize the

results, however, by assuming that the order or the numerator polynomial Y(x) is equal to the order of the denominator polynomial U(x) and making the additional coefficients $a_{m+1}, a_{m+2}, \ldots, a_n$ equal to zero. Then multiplying both the numerator and denominator of the above equation by $(g(x))^n$ gives

$$H(x) = \frac{a_0 (g(x))^n + a_1 p(x)(g(x))^{n-1} + \ldots + a_n (p(x))^n}{b_0 (g(x))^n + b_1 p(x)(g(x))^{n-1} + \ldots + b_n (p(x))^n} \qquad (1.4)$$

or, in a different form,

$$H(x) = \frac{\sum_{i=0}^{i=n} a_i \, p(x)^i g(x)^{n-i}}{\sum_{i=0}^{i=n} b_i \, p(x)^i g(x)^{n-i}} \qquad (1.5)$$

Now with the numerator and denominator of the same form, we can use the same transformation for both the numerator and denominator polynomials of the filter transfer function, namely,

$$a'(x) = a_0' + a_1' x + a_2' x^2 + \ldots + a_n' x^n = \sum_{i=0}^{i=n} a_i \, p(x)^i g(x)^{n-i} \qquad (1.6)$$

In Equation 1.6, the a_i are the coefficients of the old numerator or denominator polynomials and a_i' are the new, transformed numerator or denominator polynomial coefficients. Since the new coefficients a_i', are a linear combination of

the old coefficients a_i, and the coefficients of p(x) and q(x), this suggests the use of a matrix transformation;

$$\mathbf{a}' = \mathbf{a}\mathbf{A}(n) \tag{1.7}$$

where

a is the coefficient row vector for the old numerator or denominator polynomial of length=n+1.

$$\mathbf{a} = [a_0 \; a_1 \; a_2 \; . \; . \; . \; a_n]$$

a' is the coefficient row vector for the new numerator or denominator polynomial of length=n'+1.

$$\mathbf{a}' = [a'_0 \; a'_1 \; a'_2 \; . \; . \; . \; a_{n'}]$$

A(n) is the transformation matrix with dimensions (n+1)x(n'+1). The elements of **A**(n) depend upon the coefficients of p(x) and q(x). Note that if the rows and columns of **A**(n) are numbered 0 to n', then

$$a_j' = \sum_{i=0}^{i=n} a_i A(n)_{ij} \tag{1.8}$$

(where $A(n)_{ij}$ denotes the element in row i, column j of matrix **A**(n).)

n is the order of the transfer function before the transformation

n' is the order of the transfer function after the transformation. Note that n' equals n times the highest order of p(x) and q(x).

For example, when n=1 and n'=2, p(x) and q(x) are second order and Equation 1.7 becomes,

$$\begin{bmatrix} a_0 & a_1 \end{bmatrix} \begin{bmatrix} A(2)_{00} & A(2)_{01} & A(2)_{02} \\ A(2)_{10} & A(2)_{11} & A(2)_{12} \end{bmatrix} = \begin{bmatrix} a0' & a1' & a2' \end{bmatrix}. \tag{1.9}$$

In the case of the lowpass digital, highpass digital, and bilinear transformations, the two functions p(x) and g(x) are first order. Professor P.H. Moose of the Naval Postgraduate School of Monterey has developed the matrix A(n) for these two cases by expanding Equation 1.6 using the binomial theorem (Reference 1). This method cannot be used for transformations involving higher order polynomials such as the bandpass and bandstop transformations and it is difficult to develop because intricate manipulation of the binomial coefficients are involved. The binomial expansion approach, therefore, was not pursued.

A general method has been found that develops the required transformation matrices in an iterative manner. In other words, the matrix used to transform a numerator or denominator filter polynomial of order n is developed from the matrix for the polynomial of order n-1. This approach is easy to implement in a computer program and can be used for any of the polynomial substitutions needed. The next chapter is concerned with developing the transformation matrices for each specific transformation. However, as an introduction to the method used, consider the generic case where both p(x) and g(x) are second-order polynomials. Since all of the analog and digital transformations involve substitutions with polynomials of second order or less, this second-order generic case will be all that is needed to develop the specific transformations later.

With $p(x)=ax^2 + bx + c$, $g(x) = dx^2 + ex + f$, and substituting into Equation 1.6 for the first order case of n=1 (remembering that with p(x) and g(x) of second order, the resulting polynomial will be second order), we get

$$a'(x) = a_0' + a_1'x + a_2'x^2 = a_0(dx^2 + ex + f) + a_1(ax^2+bx+c) \tag{1.10}$$

Using Equation 1.8 or 1.9 it is easy to pick out the matrix coefficients $A(1)_{ij}$ (i=0,1; j=0,1,2) for the first order generic case. The coefficients are,

$$\mathbf{A}(1) = \begin{bmatrix} f & e & d \\ c & b & a \end{bmatrix} \tag{1.11}$$

Now with n=2 (n'=4) substituting into Equation 1.6 gives,

$$a'(x) = a_0' + a_1'x + a_2'x^2 + a_3'x^3 + a_4'x^4 \tag{1.12}$$
$$= a_0(dx^2+ex+f)^2 + a_1(ax^2+bx+c)(dx^2+ex+f) + a_2(ax^2+bx+c)^2$$

and the matrix **A**(2) is;

$$\mathbf{A}(2) = \begin{bmatrix} f^2 & 2ef & 2df+e^2 & 2de & d^2 \\ fc & ec+bf & cd+fa+eb & db+ea & da \\ c^2 & 2bc & 2ac+b^2 & 2ab & a \end{bmatrix} \tag{1.13}$$

To see how this matrix is derived from the previous one, consider the first row of the matrices in Equations 1.11 and 1.13. For both matrices, this row is multiplied by the a_0 coefficient in the old polynomial. For n=1 we have $a_0 p(x)$

and we pick out the coefficients of the powers of x (x^j) to get the matrix elements $A(n)_{0,j}$. For n=2, we have $a_0(p(x))^2$ and we do the same thing only now we have the additional factor of p(x). The matrix elements can be calculated by hand in this fashion but it requires a lot of algebra. A simpler method is to use the matrix elements of the previous matrix and get the appropriate elements by convolving coefficients. For example, consider the sequence of elements in row 0 (the top row) of A(1), namely

$$f \quad e \quad d \tag{1.14}$$

To get the elements for row 0 of A(2), we need to multiply (convolve coefficients) by another p(x). Therefore, with rows numbered 0 to n, and columns number 0 to n', we have the following.

For row 0 column 0, the appropriate matrix element is

$$A(2)_{00} = \begin{matrix} d & e & f \\ f & e & d \end{matrix} = f^2 \tag{1.15}$$

For row 0 column 1, the appropriate matrix element is

$$A(2)_{01} = \begin{matrix} & d & e & f \\ f & e & d & \end{matrix} = 2fe \tag{1.16}$$

For row 0 column 2, the appropriate matrix element is

$$A(2)_{02} = \begin{matrix} d & d & e & f \\ f & e & d & \end{matrix} = 2fd+e^2 \tag{1.17}$$

For row 0 column 3, the appropriate matrix element is

$$A(2)_{03} = \begin{matrix} & d & e & f \\ f & e & d & \end{matrix} = 2de \qquad (1.18)$$

For row 0 column 4, the appropriate matrix element is

$$A(2)_{04} = \begin{matrix} & d & e & f \\ f & e & d & \end{matrix} = d^2 \qquad (1.19)$$

This convolution of the coefficients of the old matrix with the coefficients of p(x) can be carried out for every row of the old matrix to obtain all the rows of the new matrix except the last row. In the case of the last row, we are multiplying by an additional g(x) rather than an additional p(x) and so must obtain the last row of the new matrix by convolving the coefficients of the last row of the old matrix with the coefficients of g(x).

In summary we have,

(i) for row 0 to row n-1:

-row i of A(n) = row i of A(n-1) * coefficients of p(x) (1.20)

(ii) for row n:

-row n of A(n) = row n-1 of A(n-1) * coefficients of g(x) (1.21)

where * indicates linear convolution of the coefficients.

To see how this method of convolving coefficients works, consider multiplying two polynomials:

$$f1(x) = f2(x)f3(x) \qquad (1.22)$$

Since 'x' is the independent variable, no matter what letter we use, the polynomials will remain the same. Substituting 'z^{-1}' for 'x' in the above equation gives us,

$$f1(z^{-1}) = f2(z^{-1})f3(z^{-1}) \tag{1.23}$$

and we now have the familiar form where we can either multiply the two functions of 'z' or convolve the sequences found by taking the inverse z-transform. For $f2(z^{-1})$ and $f3(z^{-1})$ we find

$$\begin{aligned} f2(z^{-1}) &= a_0 + a_1 z^{-1} + a_2 z^{-2} + \ldots + a_n z^{-n} \\ f3(z^{-1}) &= b_0 + b_1 z^{-1} + b_2 z^{-2} + \ldots + b_m z^{-m} \end{aligned} \tag{1.24}$$

It is now clear that we can find the coefficients of the product f1(x) by convolving the sequence $\{a_n\}$ with the sequence $\{b_m\}$ to produce the sequence $\{c_q\}$ where,

$$\begin{aligned} \{a_n\} &= \{a_0, a_1, a_2, a_3, \ldots, a_n\} \\ \{b_m\} &= \{b_0, b_1, b_2, b_3, \ldots, b_m\} \end{aligned}$$

and with $q = m + n$ (1.25)

$$\{c_q\} = \{c_0, c_1, c_2, c_3, \ldots, c_q\}$$

Then by taking the z-transform of the sequence $\{c_q\}$ and substituting 'x' for 'z^{-1}' we get,

$$f1(x) = c_0 + c_1 x + \ldots + c_q x^q \tag{1.26}$$

We now have a simple straight-forward method of developing the necessary transformation matrices for digital filter design by picking out the first-order transformation matrix using Equations 1.6 and 1.11, and then using the convolution of coefficients method iteratively on the rows of each successive transformation matrix with Equations 1.20 and 1.21 until the appropriate matrix **A**(n) has been generated. The next chapter will develop the transformation matrices for each of the following transformations:

- bilinear transformation
- digital lowpass prototype to digital lowpass filter
- digital lowpass prototype to digital highpass filter
- digital lowpass prototype to digital bandpass filter
- digital lowpass prototype to digital bandstop filter
- analog lowpass prototype to analog lowpass filter
- analog lowpass prototype to analog highpass filter
- analog lowpass prototype to analog bandpass filter
- analog lowpass prototype to analog bandstop filter.

We will see that some of these transformations are similar and consequently, we will not have to develop separate transformation matrices for each case.

II. DEVELOPMENT OF SPECIFIC TRANSFORMATIONS

A. INTRODUCTION

The individual transformations are discussed in the following sections. The specific form of the transformations used in each case are from Reference 2. Since the final result will be to develop a computer program to assist in the calculation of digital filter coefficients, confining the specific transformations to the form in Reference 2, will allow the computer program to be used in conjunction with Reference 2 as an aid in designing digital filters.

B. BILINEAR TRANSFORMATION

The bilinear transformation may be used to transform an analog transfer function, H(s), to a digital transfer function H(z). The transformation from H(s) to H(z) is described by

$$H(z) = H(z)\Big|_{s=\frac{z-1}{z+1}} \qquad (2.1)$$

Referring to Equation 1.1, p(x)=z-1 and g(x)=z+1. Since both of the transformation polynomials p(x) and g(x) are first order, the bilinear transformation will not change the order of the transfer function. Therefore, for an analog transfer function of order 'n', the transformation matrix **A(n)** will be

(n+1) by (n+1). From Equation 1.6, the numerator or denominator polynomial of the transfer function H(z) is given by

$$a'(z) = a_0' + a_1'z + \ldots + a_n'z^n = \sum_{i=0}^{i=n} a_i (z-1)^i (z+1)^{n-i} \qquad (2.2)$$

where the unprimed coefficients, a_i, come from the analog transfer function's numerator or denominator polynomial. In matrix form, with n=1 and referring to Equation 1.11, the first order matrix A(1) for the bilinear transformation is

$$A(1) = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \qquad (2.3)$$

Using the convolution of coefficients method developed in Chapter 1, the transformation matrix A(n+1) can be developed from the matrix A(n). The results for the bilinear transformation matrices A(1) through A(5) are given in Table 1.

TABLE 1
FIRST-ORDER TO FIFTH-ORDER BILINEAR TRANSFORMATION MATRICES

$$\mathbf{A}(1) = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$$

$$\mathbf{A}(2) = \begin{bmatrix} 1 & 2 & 1 \\ -1 & 0 & 1 \\ 1 & -2 & 1 \end{bmatrix}$$

$$\mathbf{A}(3) = \begin{bmatrix} 1 & 3 & 3 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \\ -1 & 3 & -3 & 1 \end{bmatrix}$$

$$\mathbf{A}(4) = \begin{bmatrix} 1 & 4 & 6 & 4 & 1 \\ -1 & -2 & 0 & 2 & 1 \\ 1 & 0 & -2 & 0 & 1 \\ -1 & 2 & 0 & -2 & 1 \\ 1 & -4 & 6 & -4 & 1 \end{bmatrix}$$

$$\mathbf{A}(5) = \begin{bmatrix} 1 & 5 & 10 & 10 & 5 & 1 \\ -1 & -3 & -2 & 2 & 3 & 1 \\ 1 & 1 & -2 & -2 & 1 & 1 \\ -1 & 1 & 2 & -2 & -1 & 1 \\ 1 & -3 & 2 & 2 & -3 & 1 \\ -1 & 5 & -10 & 10 & -5 & 1 \end{bmatrix}$$

Referring to Table 1 and keeping in mind the convolution of coefficients method that produced the matrices, the following relations are apparent and will be useful in computer implementation.

$$A(n)_{0,j} \text{ (the first row)} = \binom{n}{j} \quad \text{for } j=0,1,\ldots,n \tag{2.4}$$

where $\binom{n}{j}$ indicates the binomial coefficient

$$A(n)_{i,0} \text{ (the first column)} = (-1)^i \quad \text{for } i=0,1,\ldots,n \tag{2.5}$$

$$A(n)_{i,n} \text{ (the last column)} = 1 \quad \text{for } i=0,1,\ldots,n \tag{2.6}$$

$$A(n)_{(n-i),j} = (-1)^{n-j} A(n)_{i,j} \quad \text{for } i=0,1\ldots,\text{integer}(n/2)+1 \tag{2.7}$$

$$A(n)_{i,j} = A(n-1)_{i,j} + A(n-1)_{i,(j-1)} \quad \text{for } i=0,1,\ldots,n-1 \quad j=1,2,\ldots,n-1 \tag{2.8}$$

Notice that the values of the matrix elements for the bilinear transformation are whole numbers. This is important from a numerical accuracy standpoint since whole numbers can be expressed precisely in floating point form. This means that the bilinear transformation will cause a loss of accuracy of the original coefficients only because of the n+1 multiplications and additions used to calculate each new digital coefficient.

C. LOWPASS TO LOWPASS DIGITAL TRANSFORMATION

The lowpass to lowpass digital transformation is used to transform a lowpass prototype digital filter **H(z)** into a lowpass digital filter H(z). The polynomial substitution

used is

$$H(z) = H_p(z)\Big|_{z=\frac{z-\alpha}{1-\alpha z}} \qquad (2.9)$$

where the subscript p indicates the prototype digital filter transfer function. The design constant α is determined [References 2 and 3] by

$$\alpha = \frac{\sin(\theta_c/2 - \theta_c'/2)}{\sin(\theta_c/2 - \theta_c''/2)} \qquad (2.10)$$

with θ_c = the prototype critical frequency (usually pi/2) and θ_c' = the desired critical frequency of the lowpass filter. Again, referring to Equation 1.1 with $p(x) = z-\alpha$ and $g(z) = 1-\alpha z$, the lowpass digital transformation matrix will not change the order of the transfer function and the transformation matrix **A**(n) will be (n+1) by (n+1). Using Equations 1.6 and 1.11 as before, the first order transformation matrix **A**(1) for the lowpass digital transformation is:

$$A(1) = \begin{bmatrix} 1 & -\alpha \\ -\alpha & 1 \end{bmatrix} \qquad (2.11)$$

Once again using the convolution of coefficients method, the higher-order transformation matrixes **A**(n) are developed from the lower-order matrix **A**(n-1). The results are shown in Table 2 for the first-order to fifth-order transformation matrices.

TABLE 2
FIRST-ORDER TO FIFTH-ORDER LOWPASS DIGITAL
TRANSFORMATION MATRICES

$$\mathbf{A}(1) = \begin{bmatrix} 1 & -\alpha \\ -\alpha & 1 \end{bmatrix}$$

$$\mathbf{A}(2) = \begin{bmatrix} 1 & -2\alpha & \alpha^2 \\ -\alpha & (1+\alpha^2) & -\alpha \\ \alpha^2 & -2\alpha & 1 \end{bmatrix}$$

$$\mathbf{A}(3) = \begin{bmatrix} 1 & -3\alpha & 3\alpha^2 & -\alpha^3 \\ -\alpha & (1+2\alpha^2) & (-2\alpha-\alpha^3) & \alpha^2 \\ \alpha^2 & (-2\alpha-\alpha^3) & (1+2\alpha^2) & -\alpha \\ -\alpha^3 & 3\alpha^2 & -3\alpha & 1 \end{bmatrix}$$

$$\mathbf{A}(4) = \begin{bmatrix} 1 & -4\alpha & 6\alpha^2 & -4\alpha^3 & \alpha^4 \\ -\alpha & (1+3\alpha^2) & (-3\alpha-3\alpha^3) & (3\alpha^2+\alpha^4) & -\alpha^3 \\ \alpha^2 & (-2\alpha-2\alpha^3) & (1+4\alpha^2+\alpha^4) & (-2\alpha-2\alpha^3) & \alpha^2 \\ -\alpha^3 & (3\alpha^2+\alpha^4) & (-3\alpha-3\alpha^3) & (1+3\alpha^2) & -\alpha \\ \alpha^4 & -4\alpha 3 & 6\alpha^2 & -4\alpha & 1 \end{bmatrix}$$

$$\mathbf{A}(5) = \begin{bmatrix} 1 & -5\alpha & 10\alpha^2 & -10\alpha^3 & 5\alpha^4 & -\alpha^5 \\ -\alpha & (1+3\alpha^2) & (-4\alpha-6\alpha^3) & (6\alpha^2+\alpha^4) & (-4\alpha^3-\alpha^5) & \alpha 4 \\ \alpha^2 & (-2\alpha-3\alpha^3) & (1+6\alpha^2+3\alpha^4) & (-3\alpha-6\alpha^3-\alpha^5) & (3\alpha^2+2\alpha^4) & -\alpha^3 \\ -\alpha^3 & (3\alpha^2+2\alpha^4) & (-3\alpha-6\alpha^2-\alpha^5) & (1+6\alpha^2+3\alpha^4) & (-2\alpha-3\alpha^3) & \alpha 2 \\ \alpha^4 & (-4\alpha^3-\alpha^5) & (6\alpha^2+4\alpha^4) & (-4\alpha-6\alpha^3) & (1+4\alpha^2) & -\alpha \\ -\alpha^5 & 5\alpha^4 & -10\alpha^3 & 10\alpha^2 & -5\alpha & 1 \end{bmatrix}$$

Referring to Table 2, the following relations are observed and will be used in the computer implementation.

$$A(n)_{0j} \text{ (the first row)} = \binom{n}{j} (-\alpha)^j \quad \text{for } j=0,1,\ldots,n \tag{2.12}$$

$$A(n)_{i0} \text{ (the first column)} = (-\alpha)^i \quad \text{for } i=0,1,\ldots,n \tag{2.13}$$

$$A(n)_{ij} = A(n)_{(n-i)(n-j)} \quad \text{for } i,j=0,1,\ldots,n \tag{2.14}$$

$$A(n)_{ij} = A(n-1)_{(i-1)(j-1)} + (-\alpha)A(n-1)_{(i-1)j} \tag{2.15}$$
$$\text{for } i=1,2,\ldots,n-1 \quad j=1,2,\ldots,n$$

Note that the elements of the lowpass digital transformation matrices are not whole numbers as in the bilinear transformation case, but are polynomials of the design constant α. Numerical error is introduced in this case by both the n+1 additions or multiplications, and the error in calculating the matrix elements that multiply the original coefficients.

D. LOWPASS TO HIGHPASS DIGITAL TRANSFORMATION

The lowpass to highpass digital transformation is used to transform a lowpass prototype to a highpass filter. The polynomial substitution for this transformation is:

$$H(z) = H_p(z)\Big|_{z = -\frac{z-\alpha}{1-\alpha z}} \tag{2.16}$$

Since this transformation is the same as that for the lowpass to lowpass digital transformation except for the minus sign,

we can make the substitution of '-z' for 'z' in the original prototype transfer function and then use the same transformation matrices as the lowpass to lowpass case. For the lowpass to highpass transformation, the design constant α is (References 2 and 3)

$$\alpha = \frac{\cos(\Theta_c/2 - \Theta_c'/2)}{\cos(\Theta_c/2 + \Theta_c'/2)} \tag{2.17}$$

with Θc - the prototype critical frequency (usually pi/2) and $\Theta c'$ - the desired critical frequency of the highpass filter.

E. LOWPASS TO BANDSTOP DIGITAL TRANSFORMATION

The polynomial substitution which transforms a digital lowpass prototype to a bandstop digital filter is (References 2 and 3):

$$H(z) = H_p(z)\Big|_{z = \frac{z^2 - \frac{2\alpha}{1+k} z + \frac{1-k}{1+k}}{1 - \frac{2\alpha}{1+k} z + \frac{1-k}{1+k} z^2}} \tag{2.18}$$

with

$$\alpha = \frac{\cos(\Theta_u'/2 + \Theta_l'/2)}{\cos(\Theta_u'/2 - \Theta_l'/2)} \tag{2.19}$$

and

$$K = \tan(\Theta_c/2)\tan(\Theta_u'/2 - \Theta_l'/2) \tag{2.20}$$

with once again, Θ_c = the prototype critical frequency (usually pi/2), Θ_u' = the desired upper critical digital

frequency, and Θ_l' = the desired low critical digital frequency.

By letting $b = 2\alpha/(k+1)$ and $c=(1-k)/(1+k)$, Equation 2.18 can be simplified to

$$H(z) = H_p(z)\Big|_{z = \frac{z^2 - bz + c}{1 - bz + cz^2}} \tag{2.21}$$

Again, using Equations 1.6 and 1.11 the first-order transformation matrix is

$$\mathbf{A}(1) = \begin{bmatrix} 1 & -b & c \\ c & -b & 1 \end{bmatrix} \tag{2.22}$$

Note that since the substitution polynomials are second order, this transformation will double the order of the original prototype filter. Therefore, the transformation matrix $\mathbf{A}(n)$ will be (n+1) by (2n+1). The higher order transformation matricies are again developed recursively and the results for the first-order to third-order transformations are given in Table 3.

TABLE 3
FIRST-ORDER TO THIRD-ORDER BANDSTOP
DIGITAL TRANSFORMATION MATRICES

$$\mathbf{A}(1) = \begin{bmatrix} 1 & -b & c \\ c & -b & 1 \end{bmatrix}$$

$$\mathbf{A}(2) = \begin{bmatrix} 1 & -2b & (b^2+2c) & -2bc & c^2 \\ c & (-b-bc) & (1+b^2+c^2) & (-b-bc) & c \\ c^2 & -2bc & (b^2+2c) & -2c & 1 \end{bmatrix}$$

$$\mathbf{A}(3) = \begin{bmatrix} 1 & -3c & (3b^2+3c) & (-b^3-6bc) & \dots \\ c & (-2bc-b) & (1+2b^2+bc+2c) & (-b^3-2b-2bc-2bc^2) & \dots \\ c^2 & (-2bc-bc^2) & (c^3+2b^2c+2c+b^2) & \dots & \\ c^3 & -3c^2b & (3b^2c+3c^2) & \dots & \end{bmatrix}$$

(Redundant entries not shown for **A**(3) due to space limitations. Entries not shown can be found using Equation 2.25)

Notice the increased amount of calculation needed to determine the matrix elements for the bandstop case. Each matrix element is a function of 'b' and 'c' which are themselves functions of the design constants α and k. Table 3 only gives the transformation matrices for first- to third-order. However, to illustrate the amount of calculation required, the matrix element $A(5)_{25}$ is

$$A(5)_{25} = (-12bc^2-6bc^3-8b^3c-6bc-6b^3-3b-3bc^4-6b^3c^2-b^5) \quad (2.23)$$

Since each coefficient in the final filter is found by multiplying n+1 matrix elements by the n+1 original

coefficients and then adding the n+1 products, the accuracy of the design constants and the original coefficients can be critical in the calculation of the final filter coefficients.

The symmetry relations for the bandstop transformation are:

$$A(n)_{i0} \text{ (the first column)} = c^i \quad \text{for } i=0,1,\ldots,n \tag{2.24}$$

$$A(n)_{ij} = A(n)_{(n-i)(2n-j)} \quad \text{for } i=0,1,\ldots,n \quad j=0,1,\ldots,2n \tag{2.25}$$

$$A(n)_{ij} = A(n-1)_{ij} - bA(n-1)_{i(j-1)} + cA(n-1)_{i(j-2)} \quad \text{for } i=0,1,\ldots,n-1 \quad j=0,1,\ldots,2n \tag{2.26}$$

F. LOWPASS TO BANDPASS DIGITAL TRANSFORMATION

Again, the polynomial substitution which transforms the lowpass prototype to a bandpass filter is

$$H(z) = H_p(z)\Big|_{z = -\dfrac{z^2 - \frac{2\alpha k}{k+1} z + \frac{k-1}{k+1}}{1 - \frac{2\alpha k}{k+1} z + \frac{k-1}{k+1} z^2}} \tag{2.27}$$

where in this case $k = \tan(\Theta/2)\cot(\Theta_u'/2 - \Theta_l'/2)$ and α is found from the same expression as the bandstop case. With the simplification of $b=2\alpha k/(k+1)$ and $c=(k-1)/(k+1)$, Equation 2.27 becomes

$$H(z) = H_p(z)\Big|_{z = -\frac{z^2 - bz + c}{1 - bz + cz^2}} \qquad (2.28)$$

Since this is the same form as the bandstop transformation, we can use the matrices previously developed if '-z' is first substituted for 'z' as was done in the lowpass and highpass situation.

G. LOWPASS TO LOWPASS ANALOG TRANSFORMATION

The lowpass to lowpass analog transformation is used to transform an analog lowpass prototype to a lowpass analog filter. The polynomial substitution is a simple one, namely

$$H(s) = H_p(s)\Big|_{s = s/w_c} \qquad (2.29)$$

where w_c is the prewarped critical frequency ($w_c = \tan(\Theta_c/2)$ and Θ_c is the desired digital critical frequency ($\Theta_c = 2(pi)f_c/f_s$). This transformation matrix is found to be

$$\mathbf{A}(n) = \begin{bmatrix} 1 & 0 & 0 & \cdots & 0 \\ 0 & 1/w_c & 0 & \cdots & 0 \\ 0 & 0 & 1/w_c^2 & \cdots & 0 \\ \vdots & & & & \\ 0 & 0 & 0 & \cdots & 1/w_c^n \end{bmatrix}$$

or $\mathbf{A}(n) = \text{diag}(1, 1/w_c, 1/w_c^2, \ldots, 1/w_c^n)$ throughout. (2.30)

Note that in this case, each new filter coefficient depends only on multiplying the old coefficient of s^1 by $(w_c)^{-1}$. Therefore, any loss of accuracy due to the transformation is due to this one multiplication and the error introduced in calculation of the matrix element $(w_c)^{-1}$.

H. LOWPASS TO HIGHPASS ANALOG TRANSFORMATION

The polynomial substitution for the lowpass to highpass transformation is

$$H(s) = H_p(s)\Big|_{s = w_c/s} \tag{2.31}$$

Again using Equations 1.6 and 1.11, the first-order transformation matrix is

$$A(1) = \begin{bmatrix} 0 & 1 \\ w_c & 0 \end{bmatrix} \tag{2.32}$$

The method of convolution of coefficients can be used to get the higher-order transformation matrices. However, notice that Equation 2.32 is the same matrix as the lowpass to lowpass transformation with the reciprocal taken of each non zero element, and then each row reversed. This can be shown to be the case in general, so that the lowpass to highpass transformation matrix is given by

$$\mathbf{A}(n) = \begin{bmatrix} 0 & 0 & \cdots & 0 & 1 \\ 0 & 0 & \cdots & w_c & 0 \\ \vdots & & & & \\ 0 & w_c^{n-1} & \cdots & 0 & 0 \\ w_c^{n} & 0 & \cdots & 0 & 0 \end{bmatrix} \qquad (2.33)$$

Again, each new filter coefficient depends only on one multiplication although the calculation of the matrix element itself will require calculations involving raising the design constant, w_c, to the $(n-1)^{th}$ power where i is the power of s in the final filter transfer function.

I. LOWPASS TO BANDPASS ANALOG TRANSFORMATION

The polynomial substitution for transforming a lowpass analog prototype to a bandpass analog filter is

$$H(s) = H_p(s)\Big|_{s = \frac{s^2 + w_o^2}{Bs}} \qquad (2.34)$$

where wo is defined as the geometric mean of the passband; $w_o = (w_u w_l)^{\frac{1}{2}}$, and B is the width of the passband, $B = w_u - w_l$. (w_u and w_l are the upper and lower critical frequencies respectively). Again using Equations 1.6 and 1.11 and picking out the appropriate matrix elements, the first-order transformation matrix is given by

$$\mathbf{A}(1) = \begin{bmatrix} 0 & B & 0 \\ w_o^2 & 0 & 1 \end{bmatrix} \tag{2.35}$$

The convolution of coefficients technique is again used to generate the higher order transformation matrices with the results for the first-order to third-order matrices listed in Table 4. As with the bandpass digital transformation, the analog bandpass transformation will double the order of the original transfer function since the substitution polynomial is of second order.

TABLE 4
FIRST-ORDER TO THIRD-ORDER BANDPASS
ANALOG TRANSFORMATION MATRICES

$$\mathbf{A}(1) = \begin{bmatrix} 0 & B & 0 \\ w_o^2 & 0 & 1 \end{bmatrix}$$

$$\mathbf{A}(2) = \begin{bmatrix} 0 & 0 & B^2 & 0 & 0 \\ 0 & Bw_o^2 & 0 & B & 0 \\ w_o^4 & 0 & 2w_o^2 & 0 & 1 \end{bmatrix}$$

$$\mathbf{A}(3) = \begin{bmatrix} 0 & 0 & 0 & B^3 & 0 & 0 & 0 \\ 0 & 0 & B^2 w_o^2 & 0 & B^2 & 0 & 0 \\ 0 & Bw_o^4 & 0 & 2Bw_o^2 & 0 & B & 0 \\ w_o^6 & 0 & 3w_o^4 & 0 & 3w_o^2 & 0 & 1 \end{bmatrix}$$

Note that each matrix is slightly over half empty and that the nonzero elements are simple functions of the design constants w_o and B.

J. LOWPASS TO BANDSTOP ANALOG TRANSFORMATION

For the analog bandstop transformation, the polynomial substitution is the reciprocal of the bandpass case:

$$H(s) = H_p(s)\Big|_{s = \frac{Bs}{s^2 + w_o^2}} \tag{2.36}$$

Using the same method as before, the first-order transformation matrix is found to be:

$$A(1) = \begin{bmatrix} w_o^2 & 0 & 1 \\ 0 & B & 0 \end{bmatrix} \tag{2.37}$$

Note that this is the same matrix as the bandpass case but with the rows in reverse order. Using the convolution of coefficients technique the higher-order matrices are developed and the results for the first-order to third-order transformation matrices are shown in Table 5. Notice that the reversal of the order of the rows compared with the bandpass case is true in general. Therefore, once again the matrices are over half empty and nonzero elements are simple functions of B and w_o.

TABLE 5
FIRST-ORDER TO THIRD-ORDER BANDSTOP
ANALOG TRANSFORMATION MATRICES

$$\mathbf{A}(1) = \begin{bmatrix} w_o^2 & 0 & 1 \\ 0 & B & 0 \end{bmatrix}$$

$$\mathbf{A}(2) = \begin{bmatrix} w_o^4 & 0 & 2w_o^2 & 0 & 1 \\ 0 & Bw_o^4 & 0 & B & 0 \\ 0 & 0 & B^2 & 0 & 0 \end{bmatrix}$$

$$\mathbf{A}(3) = \begin{bmatrix} w_o^6 & 0 & 2w_o^4 & 0 & 3w_o^{22} & 0 & 1 \\ 0 & Bw_o^4 & 0 & 2Bw_o^2 & 0 & B & 0 \\ 0 & 0 & B^2 w_o^2 & 0 & B^2 & 0 & 0 \\ 0 & 0 & 0 & B^3 & 0 & 0 & 0 \end{bmatrix}$$

K. GENERAL OBSERVATIONS

Now that the various transformation matrices for digital filter design have been developed, it is possible to compare the two methods of digital filter design mentioned earlier and depicted in Figure 1. For this comparison, consider an analog lowpass prototype filter transfer function with numerator of order m, and denominator of order n (m less than or equal to n).

First consider the digital to digital direct design method. Transforming the analog prototype to a digital prototype using the bilinear transformation will require m+1

multiplications and additions per digital prototype coefficient for the numerator polynomial, and n+1 multiplications and additions per digital prototype coefficient for the denominator polynomial. Then, each of the digital to digital transformations will require 2(n+1) multiplications and additions since a result of the bilinear transformation is to make n = m. Therefore, going from an analog prototype to a final digital filter will require (3n+m+4) multiplications and additions. If lowpass digital prototypes are developed prior to the design process, this can be reduced to 2(n+1) since then only the digital to digital transformations will be used in designing the final filter.

Now consider the analog design method for the same case of an m^{th} -order numerator and n^{th} -order denominator lowpass prototype transfer function. For the lowpass and highpass case, each new coefficient will require only 1 multiplication and addition. For the bandpass and bandstop transformations a simple expression for the number of calculations per coefficient is difficult to find, however referring to Tables 4 and 5, the number of multiplications and additions per coefficient is always less than half the order of the polynomial to be transformed, on the average. This gives approximately (n+m)/2 for the bandpass to bandstop analog transformations. Finally the analog filter must be converted to a digital filter using the bilinear transformation which

will require (n+m+2) calculations per coefficient for the highpass and lowpass case and 2(n+m+1) for the bandpass and bandstop case. The total number of calculations in using the analog design method then is (n+m+4) for the high/low pass and (2.5(n+m)+2) for the bandpass/stop. These results are summarized in Table 6.

TABLE 6
NUMBER OF MULTIPLICATIONS AND ADDITIONS REQUIRED PER COEFFICIENT TO FIND THE DIGITAL FILTER COEFFICIENTS FROM A LOWPASS ANALOG PROTOTYPE (WITH AN M^{TH} ORDER NUMERATOR AND N^{TH} ORDER DENOMINATOR)

	Analog Design	
	high/low pass	bandpass/stop
analog transformations	2	.5(n+m)
bilinear transformation	n+m+2	2(n+m)+2
Total	n+m+4	2.5(n+m)+2

	Digital Design	
	high/low pass	bandpass/stop
bilinear transformation	n+m+2	n+m+2m
digital transformations	2(n+1)	2(n+1)
Total	3(n+1)+m+1	3(n+1)+m+1

Referring to Table 6, the advantage of one method over the other depends upon what type of filter is being designed and the order of the prototype transfer functions numerator and denominator. Consider designing a fifth-order low/highpass Chebyshev or Butterworth filter. In this case, the order of the numerator polynomial is zero and the analog method will have a slight advantage of 9 multiplications and additions versus 12 for the digital design with precalculated prototypes (and 19 for digital design without precalculated prototypes). However, if a bandpass/stop elliptic filter was being designed with n=5, then m=4 and the direct digital design method (with precalculated prototypes) has an advantage of 12 multiplications and additions compared to approximately 24 for the analog method.

A final consideration in favor of analog design is the complexity of the elements of the transformation matrices. Since the elements of the digital transformation matrices require much more calculation than the elements of the analog transformation matrices or the bilinear transformation (compare Tables 1-5), the problem of roundoff error is much more serious in the case of the digital to digital design method.

L. IMPLEMENTATION

The final step is to implement the algorithms developed previously in a computer program to assist in the teaching of digital filter design. Since the program is intended to be

used for instructional purposes, the numerical considerations discussed earlier are not considered as important as conceptual simplicity. The direct design method was chosen for implementation as the design constants can be found easily without reference to "prewarping." The completed program, called 'DFCADD' (Digital Filter Computer Aided Direct Design), is contained in Appendix A with its own documentation. The program follows the procedures set forth in Chapter 10 of Reference 2. Prototype coefficients are stored within the program for first-order to fifth-order Butterworth and Chebyshev (1/2,1,&2dB ripples) filters. While second-order to sixth-order elliptic lowpass prototype coefficients are calculated within the program for any combination of 1/2,1,2, and 3 dB passband ripple and -20,-30,-40,-50,-60, and -70 dB stopband attenuation, with the help of a program developed by Professor D.E. Kirk of the Naval Postgraduate School and References 4 and 5. As a final option, the user may enter his/her own prototype coefficients for up to a tenth-order analog prototype. After calculating the digital filter coefficients an option exists for the program to create a data file, titled "filter", with the digital filter magnitude and phase as a function of the digital frequency from zero to pi. This data file can then be used with any plotting routine to generate a plot of the frequency response of the filter.
